(54) Title: HETEROARYL SUBSTITUTED SPIROCICLIC SULFAMIDES FOR INHIBITION OF GAMMA SECRETASE

(I)

(57) Abstract: Compounds of formula I are disclosed: in which X is a 5-membered heteroaryl ring and R is as defined herein. The compounds are inhibitors of the processing of APP by gamma-secretase, and hence are useful in the treatment or prevention of Alzheimer's disease.

WO 03/093252 A1

**HETEROARYL SUBSTITUTED SPIROCYCLIC SULFAMIDES FOR
INHIBITION OF GAMMA SECRETASE**

The present invention relates to a novel class of compounds, their salts, pharmaceutical compositions comprising them, processes for making
5 them and their use in therapy of the human body. In particular, the invention relates to compounds which modulate the processing of APP by γ -secretase, and hence are useful in the treatment or prevention of Alzheimer's disease.

Alzheimer's disease (AD) is the most prevalent form of dementia.
10 Although primarily a disease of the elderly, affecting up to 10% of the population over the age of 65, AD also affects significant numbers of younger patients with a genetic predisposition. It is a neurodegenerative disorder, clinically characterized by progressive loss of memory and cognitive function, and pathologically characterized by the deposition of
15 extracellular proteinaceous plaques in the cortical and associative brain regions of sufferers. These plaques mainly comprise fibrillar aggregates of β -amyloid peptide ($A\beta$), and although the exact role of the plaques in the onset and progress of AD is not fully understood, it is generally accepted that suppressing or attenuating the secretion of $A\beta$ is a likely means of
20 alleviating or preventing the condition. (See, for example, *ID research alert* 1996 1(2):1-7; *ID research alert* 1997 2(1):1-8; *Current Opinion in CPNS Investigational Drugs* 1999 1(3):327-332; and *Chemistry in Britain*, Jan. 2000, 28-31.)

$A\beta$ is a peptide comprising 39-43 amino acid residues, formed by
25 proteolysis of the much larger amyloid precursor protein. The amyloid precursor protein (APP or $A\beta$ PP) has a receptor-like structure with a large ectodomain, a membrane spanning region and a short cytoplasmic tail. Different isoforms of APP result from the alternative splicing of three exons in a single gene and have 695, 751 and 770 amino acids respectively.

30 The $A\beta$ domain encompasses parts of both extra-cellular and transmembrane domains of APP, thus its release implies the existence of

two distinct proteolytic events to generate its NH₂- and COOH-termini. At least two secretory mechanisms exist which release APP from the membrane and generate the soluble, COOH-truncated forms of APP (APP_s). Proteases which release APP and its fragments from the
5 membrane are termed "secretases". Most APP_s is released by a putative α -secretase which cleaves within the A β domain (between residues Lys¹⁶ and Leu¹⁷) to release α -APP_s and precludes the release of intact A β . A minor portion of APP_s is released by a β -secretase, which cleaves near the NH₂-terminus of A β and produces COOH-terminal fragments (CTFs) which
10 contain the whole A β domain. Finding these fragments in the extracellular compartment suggests that another proteolytic activity (γ -secretase) exists under normal conditions which can generate the COOH-terminus of A β .

It is believed that γ -secretase itself depends for its activity on the
15 presence of presenilin-1. In a manner that is not fully understood presenilin-1 appears to undergo autocleavage.

There are relatively few reports in the literature of compounds with inhibitory activity towards β - or γ -secretase, as measured in cell-based assays. These are reviewed in the articles referenced above. Many of the
20 relevant compounds are peptides or peptide derivatives.

WO 01/70677 discloses certain sulphonamido-substituted bridged bicycloalkyl derivatives which are useful in the treatment of Alzheimer's disease, but neither discloses nor suggests the compounds of the present invention.

25 The present invention provides a novel class of non-peptidic compounds which are useful in the treatment or prevention of AD by modulating the processing of APP by the putative γ -secretase, thus arresting the production of A β and preventing the formation of insoluble plaques.

30 According to the invention there is provided a compound of formula I:

I

wherein the moiety X-R is attached at one of the positions indicated by an asterisk;

X is a bivalent pyrazole, imidazole, triazole, oxazole, isoxazole, thiazole, isothiazole, thiadiazole or 1,3,4-oxadiazole residue optionally bearing a hydrocarbon substituent comprising 1-5 carbon atoms which is optionally substituted with up to 3 halogen atoms; and

R is selected from:

- (i) CF_3 or a non-aromatic hydrocarbon group of up to 10 carbon atoms, optionally substituted with halogen, CF_3 , CHF_2 , CN, OH, CO_2H , $\text{C}_{2-6}\text{acyl}$, $\text{C}_{1-4}\text{alkoxy}$ or $\text{C}_{1-4}\text{alkoxycarbonyl}$;

 - (iii) phenyl or 6-membered heteroaryl, either of which bears 0-3 substituents independently selected from halogen, CF_3 , CHF_2 , CH_2F , NO_2 , CN, OCF_3 , $\text{C}_{1-6}\text{alkyl}$ and $\text{C}_{1-6}\text{alkoxy}$; and
 - (iv) $\text{N}(\text{R}^a)_2$ where each R^a independently represents H or $\text{C}_{1-6}\text{alkyl}$ which is optionally substituted with halogen, CF_3 , CHF_2 , CN, OH, CO_2H , $\text{C}_{2-6}\text{acyl}$, $\text{C}_{1-4}\text{alkoxy}$ or $\text{C}_{1-4}\text{alkoxycarbonyl}$;
- or a pharmaceutically acceptable salt thereof.

In a subset of the compounds of formula I, X is a bivalent pyrazole, imidazole, triazole, oxazole, isoxazole, thiazole, isothiazole, thiadiazole or 1,3,4-oxadiazole residue wherein, in the case of pyrazole, imidazole and triazole, one of the ring nitrogen atoms optionally bears a hydrocarbon

substituent comprising 1-5 carbon atoms which is optionally substituted with up to 3 halogen atoms; and

R is selected from:

- (i) a non-aromatic hydrocarbon group of up to 10 carbon atoms, optionally substituted with halogen, CF₃, CHF₂, CN, OH, CO₂H, C₂₋₆acyl, C₁₋₄alkoxy or C₁₋₄alkoxycarbonyl;

It will be readily apparent to those skilled in the art that the compounds of formula I exist in two enantiomeric forms, depending on which of the ring positions indicated by an asterisk is bonded to the moiety -X-R. Attachment at the position indicated by the upper asterisk in formula I gives rise to a 2-substituted-[6S,9R,11R] 2',3',4',5,5',6,7,8,9,10-decahydro-5'-(2,2,2-trifluoroethyl)-spiro[6,9-methanobenzocyclooctene-11,3'-[1,2,5]thiadiazole] 1',1'-dioxide. Conversely, attachment at the position indicated by the lower asterisk in formula I gives rise to a 2-substituted-[6R,9S,11S] 2',3',4',5,5',6,7,8,9,10-decahydro-5'-(2,2,2-trifluoroethyl)-spiro[6,9-methanobenzocyclooctene-11,3'-[1,2,5]thiadiazole] 1',1'-dioxide. It is to be emphasised that the invention, for each identity of -X-R, encompasses both enantiomers, either as homochiral compounds or as mixtures of enantiomers in any proportion. Furthermore, structural formulae depicting attachment of -X-R or a synthetic precursor thereof at

one of the said ring positions shall hereinafter be indicative of attachment at either of said ring positions, unless expressly stated otherwise.

Where a variable occurs more than once in formula I or in a substituent thereof, the individual occurrences of that variable are
5 independent of each other, unless otherwise specified.

10 Reaction of sulphonamides IV(a) with $\text{CF}_3\text{CH}_2\text{NH}_2$, followed by cleavage of the t-butylsulphonyl group, provides diamines V:

where Y has the same meaning as before. Ring-opening of the aziridine is typically effected by heating with $\text{CF}_3\text{CH}_2\text{NH}_2$ at 100°C in DMF or DMSO in a sealed tube, while cleavage of the t-butylsulphonyl group may be effected by treatment with trifluoromethanesulphonic acid at 0-20°C.

Alternatively, the diamines V may be formed directly by reaction of the sulphinamides IV(b) with $\text{CF}_3\text{CH}_2\text{NH}_2$ in the presence of zinc iodide in dichloroethane at 75°C.

Reaction of diamines V with sulphamide ($\text{H}_2\text{NSO}_2\text{NH}_2$) in refluxing anhydrous pyridine provides the cyclic sulphamides VI(a)-(c):

VI

Compounds VI(a)-(c) are key intermediates for the preparation of compounds of formula I since the substituent Y may be transformed into the moiety $-\text{X}-\text{R}$ by various standard synthetic techniques.

Hydrolysis of the esters VI(a) (for example, using sodium hydroxide in aqueous THF at 60°C) provides the acid VII which serves as the precursor for a variety of heteroaryl structures.

VII

10

In one process, the acid VII is coupled with a hydrazide $\text{R}-\text{CO}-\text{NHNH}_2$ and then reacted (a) with Burgess reagent or (b) with diphosphorus pentasulphide or Lawesson's reagent to provide, respectively, a 1,3,4-oxadiazole derivative IX(a) or a 1,3,4-thiadiazole derivative IX(b):

IX (a) Z = O
(b) Z = S

where R has the same meaning as before. The initial coupling may be effected using HBTU in the presence of a tertiary amine in acetonitrile at

40°C. Treatment with Burgess reagent may be carried out in THF using microwave heating, and treatment with diphosphorus pentasulphide may be carried out in refluxing pyridine.

In another process, the acid VII is first reacted with
 5 carbonyldiimidazole and then with an anion derived from an acetyl derivative $R-COCH_3$. Treatment of the resulting β -diketone with R^1NHNH_2 then provides the preferred pyrazoles X(a) and X(b):

X(a)

X(b)

where R^1 is H or a hydrocarbon group of up to 5 carbon atoms optionally
 10 substituted with up to 3 halogen atoms (preferably methyl) and R has the same meaning as before (preferably substituted phenyl). The anion is typically generated by treatment of $R-COCH_3$ with lithium diisopropylamide in THF at $-78^\circ C$ and reacted *in situ*. Reaction with the hydrazine is conveniently carried out in refluxing ethanol. When R^1 is
 15 other than H, the positional isomers X(a) and X(b) are formed in approximately equal proportions, and may be separated by preparative HPLC.

In another process, the acid VII is coupled with an amine $R-COCH_2NH_2$, then treated (a) with Burgess reagent or (b) with
 20 Lawesson's reagent to provide, respectively, an oxazole derivative XI(a) or a thiazole derivative XI(b):

where R has the same meaning as before. The initial coupling may be effected using HBTU in the presence of a tertiary amine in acetonitrile at 50°C. Treatment with Burgess reagent may be carried out in THF using microwave heating, and treatment with Lawesson's reagent may be carried out in refluxing toluene.

For the synthesis of oxazoles or thiazoles of formula XI in which R is N(R^a)₂ or N-heterocyclyl, it is advantageous to carry out the initial coupling of the acid VII with glycine ethyl ester, and to react the product with (R³)₂NH, where the R³ groups represent R^a (as defined previously) or complete a heterocyclic ring within the definition of R. Treatment of the resulting bis-amides with Burgess reagent or Lawesson's reagent, as described above, then provides the desired oxazoles or thiazoles.

In another process, the acid VII is converted to the corresponding hydrazide, then reacted with a thioamide R-CS-NH₂ to form a 1,2,4-triazole derivative XII:

where R has the same meaning as before. Conversion of VII to the hydrazide is conveniently effected by treatment with BOC-NHNH₂ in the presence of HBTU and a tertiary amine in acetonitrile at 20°C, followed by cleavage of the BOC protecting group with HCl at ambient temperature in ethyl acetate. Reaction with R-CS-NH₂ is carried out at elevated temperature, e.g. 200°C.

Alternatively, the acid VII (or its ester precursor VI(a)) may be reduced to the corresponding aldehyde and treated with R^1NHNH_2 to provide the corresponding hydrazone, then reacted with a hydroximinoyl chloride $R-C(Cl)=NOH$ to provide a 1,2,4-triazole XIII:

XIII

5

where R and R¹ have the same meanings as before. The aldehyde is conveniently formed by reduction of VI(a) with diisobutylaluminium hydride at -78 to -10°C in THF to provide the benzyl alcohol, which is then oxidised to the aldehyde using pyridinium dichromate in dichloromethane at room temperature. Formation of the hydrazone takes place in THF at room temperature, while the final step may be carried out in THF at -10 to 20°C in the presence of triethylamine, followed by refluxing in acetic acid.

10

The nitro derivative VI(b) may be reduced (e.g. using zinc and acetic acid) to the aniline XV:

15

XV

which is a precursor for certain compounds of formula I in which X is bonded through nitrogen. For example, diazotisation of XV followed by reaction with azide ion provides the corresponding azide, which may undergo cycloaddition with an alkyne $R-C\equiv CH$ to form a 1,2,3-triazole XVI:

20

XVI

where R has the same meaning as before. Diazotisation may be carried out under standard conditions (sodium nitrite in aqueous HCl at 0°C), and reaction of the diazonium salt with azide ion is typically carried out *in situ*. Cycloaddition with R-C≡CH may be carried out by refluxing in xylene.

The benzyl ether VI(c) may be converted to the corresponding phenol by hydrogenation over Pd/C, and thence to the triflate XVII by treatment with triflic anhydride in the presence of pyridine in dichloromethane at 0-20°C:

XVII

where Tf represents triflyl (i.e. trifluoromethanesulphonyl). The triflate XVII is another precursor of compounds in accordance with formula I.

For example, treatment of XVII with trimethylsilylacetylene in the presence of a Pd(0) catalyst, CuI and an amine, followed by treatment with lithium hydroxide, provides the corresponding acetylene derivative, which undergoes cycloaddition with nitrile oxides R-C≡N⁺-O⁻ to provide isoxazoles XVIII:

XVIII

where R has the same meaning as before. Cycloaddition of R-N₃ to the aforesaid acetylene derivative (e.g. by refluxing in xylene) provides the 1-(R-substituted)-1,2,3-triazol-4-yl isomers of XVI, where R is preferably optionally-substituted hydrocarbon, C-heterocyclyl, phenyl or heteroaryl.

5 Alternatively, XVII may be converted to a boronic acid derivative XIX:

XIX

where R² represents H or alkyl, or the two OR² groups complete a cyclic boronate ester such as the pinacolate or the neopentyl glycolate. The conversion may be achieved by conventional means using a suitable boron reagent, such as bis(pinacolato)diboron, in the presence of a Pd catalyst such as bis(diphenylphosphinoferrocene)dichloropalladium(II) or tetrakis(triphenylphosphine)palladium(0), typically in the presence of an inorganic base such as potassium acetate or sodium carbonate, in a solvent
15 such as DMF or toluene at about 100°C.

Reaction of boronates XIX with R-X-L, where L is a suitable leaving group (such as halogen, especially bromine or iodine, triflate or nonaflate) and R and X have the same meanings as before, provides compounds of formula I directly. The reaction takes place under similar conditions in
20 the presence of the same Pd catalysts as used in the preparation of XIX.

As an example of this strategy, boronate XIX may be reacted with a bromoimidazole XX:

XX

where R has the same meaning as before. Removal of the dimethylaminosulphonyl protecting group (e.g. by reflux in a mixture of THF and hydrochloric acid) then provides a compound of formula I in which R-X- represents a 4-substituted-1H-imidazol-2-yl moiety.

5 Other notable examples of compounds R-X-L which may similarly undergo coupling via boronates XIX include 4-bromo-1-(R-substituted) imidazoles and 3-bromo-1-(R-substituted)-1,2,4-triazoles, where R is preferably optionally-substituted hydrocarbon, C-heterocyclyl, phenyl or heteroaryl.

10 When the group X comprises an NH functionality in the ring (as in imidazole, for example), reaction of boronic acid XIX ($R^2 = H$) with R-X-H provides compounds of formula I in which X is bonded to the fused benzene ring through nitrogen. The reaction takes place at ambient temperature in dichloromethane in the presence of di- μ -hydroxo-bis(*N,N,N',N'*-
15 tetramethylethylenediamine)copper(II) chloride.

Alternatively, the R-X moiety may be assembled in a three-stage process in which firstly an HX- group is introduced by reaction of boronate XIX with HX-L, where L and X have the same meanings as before; secondly, the resulting product is brominated to convert the HX- group to
20 Br-X-; and thirdly, reaction with R-B(OR²) provides a compound of formula I, where R and R² have the same meanings as before.

In another process, the triflate VI(c) is reacted with tributyl(1-ethoxyvinyl)tin to form the acetyl derivative XXI(a):

XXI

- (a) W = COCH₃
- (b) W = COCH₂CHOH-R
- (c) W = COCH=CH-R
- (d) W = COCH₂CO₂Et

25

The reaction takes place in DMF in a sealed tube at 100°C in the presence of LiCl, triphenylphosphine and Pd(II)acetate. Aldol

condensation of XXI(a) with R-CHO provides the hydroxyketone XXI(b), which may be dehydrated to the enone XXI(c), where R has the same meaning as before. The aldol condensation takes place at low temperature (e.g. -78°C) in THF in the presence of a strong base such as lithium bis(trimethylsilyl)amide. The dehydration may be effected by treatment with cerium(III) chloride and sodium iodide in refluxing acetonitrile.

Reaction of the enones XXI(c) with hydrazines R^1NHNH_2 , where R^1 has the same meaning as before, followed by oxidation of the resulting adduct with DDQ, provides an alternative route to the pyrazoles X(a) and X(b), with X(a) as the major product. The reaction with the hydrazine takes place at ambient temperature in ethanol under nitrogen, while the oxidation may be carried out in THF at ambient temperature.

In another route to the pyrazoles X(a), the carboxylic acid VII is converted to the acid chloride, then added to a mixture of ethyl hydrogen malonate and isopropylmagnesium bromide at -78°C in THF, followed by treatment with aqueous HCl, to form the β -ketoester XXI(d). Reaction of this intermediate with R^1NHNH_2 (e.g. in acetic acid at ambient temperature) provides pyrazolones XXII:

XXII

where R^1 has the same meaning as before, which form the triflates XXIII by treatment with triflic anhydride and pyridine in dichloromethane at -78°C :

XXIII

where R^1 has the same meaning as before. Triflates XXIII react with $R-B(OR^2)_2$ as described previously to form pyrazoles X(a).

In another route to the pyrazoles X(a), boronic acid derivative XIX is
 5 reacted with a compound XXIV under the conditions described previously:

XXIV

where L, R and R^1 have the same meanings as before. Compounds XXIV
 10 in which L is triflate or nonaflate are accessible from the reaction of
 alkynes $R-C\equiv C-CO_2Me$ with R^1NHNH_2 and treatment of the resulting
 pyrazolones with triflic anhydride or nonafluorobutanesulfonyl fluoride
 respectively. Compounds XXIV in which L is Br are available by reaction
 of nonaflates XXV with $RZnBr$:

15

XXV

where Nf represents nonafluorobutanesulfonyl, and R and R^1 have the
 same meaning as before.

It will be apparent to those skilled in the art that in the above-described routes to compounds of formulae IX, X, XII, XIII, XVI and XVIII, or in the routes involving $R-B(OR^2)_2$, R is most suitably an optionally-substituted hydrocarbon, C-heterocyclyl, phenyl or heteroaryl group, and
5 in particular an optionally-substituted phenyl or heteroaryl group.

It is emphasised that the above formulae II – VII, IX – XIII, XV – XIX and XXI – XXIII represent both of the enantiomeric forms arising from the overall asymmetry of the molecules, either singly or in mixtures of any proportion.

10 It will be apparent to those skilled in the art that, in many cases, the steps in the synthetic schemes described above may be carried out in a different order. Thus, if desired, the group Y in ketones II may be converted to the moiety R-X- by one of the described routes prior to the construction of the spiro-linked sulphamide ring.

15 It will also be appreciated that where more than one isomer can be obtained from a reaction then the resulting mixture of isomers can be separated by conventional means.

Where the above-described process for the preparation of the compounds according to the invention gives rise to mixtures of
20 stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. The novel compounds may be prepared in racemic form, or individual enantiomers may be prepared either by enantiospecific synthesis or by resolution. The novel compounds may, for example, be resolved into their component enantiomers by
25 standard techniques such as preparative HPLC, or the formation of diastereomeric pairs by salt formation with an optically active acid, such as (-)-di-p-toluoyl-d-tartaric acid and/or (+)-di-p-toluoyl-l-tartaric acid, followed by fractional crystallization and regeneration of the free base. The novel compounds may also be resolved by formation of diastereomeric
30 esters or amides, followed by chromatographic separation and removal of

the chiral auxiliary. Alternatively, such techniques may be carried out on racemic synthetic precursors of the compounds of interest.

In a preferred route to enantiomerically pure compounds of formula I, racemic intermediates VI(a) or VI(c) are subjected to preparative chiral
5 HPLC to provide the corresponding homochiral intermediates, which are then converted to homochiral compounds of formula I by the routes indicated above.

Alternatively, intermediate II (Y = nitro) is reduced to the corresponding racemic aniline, and resolved via salt formation with (+) or
10 (-) mandelic acid. The resulting homochiral aniline is converted to the corresponding phenol (via the corresponding diazonium salt) and thence to the homochiral benzyl ether II (Y = benzyloxy), which may then be converted to homochiral compounds of formula I by the methods outlined above.

15 Where they are not commercially available, the starting materials and reagents used in the above-described synthetic schemes may be prepared by conventional means. The ketones II may be prepared by the method described in *J.Org.Chem.*, 47, 4329-34, 1982.

During any of the above synthetic sequences it may be necessary
20 and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in *Protective Groups in Organic Chemistry*, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, *Protective Groups in Organic Synthesis*, John Wiley & Sons,
25 1991. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

An assay which can be used to determine the level of activity of compounds of the present invention is described in WO01/70677. A preferred assay to determine such activity is as follows:

- 1) SH-SY5Y cells stably overexpressing the β APP C-terminal fragment SPA4CT, are cultured at 50-70% confluency. 10mM sodium butyrate is added 4 hours prior to plating.
- 2) Cells are plated in 96-well plates at 35,000 cells/well/100 μ L in
5 Dulbeccos minimal essential medium (DMEM) (phenol red-free) + 10% foetal bovine serum (FBS), 50mM HEPES buffer (pH7.3), 1% glutamine.
- 3) Make dilutions of the compound plate. Dilute stock solution 18.2x to 5.5% DMSO and 11x final compound concentration. Mix compounds vigorously and store at 4°C until use.
- 10 4) Add 10 μ L compound/well, gently mix and leave for 18h at 37°C, 5% CO₂.
- 5) Prepare reagents necessary to determine amyloid peptide levels, for example by Homogeneous Time Resolved Fluorescence (HTRF) assay.
- 6) Plate 160 μ L aliquots of HTRF reagent mixture to each well of a
15 black 96-well HTRF plate.
- 7) Transfer 40 μ L conditioned supernatant from cell plate to HTRF plate. Mix and store at 4°C for 18 hours.
- 8) To determine if compounds are cytotoxic following compound administration, cell viability is assessed by the use of redox dye reduction.
20 A typical example is a combination of redox dye MTS (Promega) and the electron coupling reagent PES. This mixture is made up according to the manufacturer's instructions and left at room temperature.
- 9) Add 10 μ L/well MTS/PES solution to the cells; mix and leave at 37°C.
- 25 10) Read plate when the absorbance values are approximately 0.4 – 0.8. (Mix briefly before reading to disperse the reduced formazan product).
- 11) Quantitate amyloid beta 40 peptide using an HTRF plate reader.
Alternative assays are described in *Biochemistry*, **2000**, 39(30), 8698-8704.

The compounds of the present invention show unexpectedly high affinities as measured by the above assays. Thus the following Examples all had an ED₅₀ of less than 50nM, typically less than 10nM, and frequently less than 1nM in at least one of the above assays. In general, the compounds also exhibit good oral bioavailability and/or brain penetration, and are largely free from undesirable biological interactions likely to lead to toxic side effects.

The following examples illustrate the present invention.

Alternative Method

2-Amino-11-oxo-5,6,7,8,9,10-hexahydro-6,9-
10 methanobenzocyclooctene (*J. Org. Chem.* **47**, 4329, 1982), (17.16 g, 0.085 mol) was dissolved in ethanol (430 mL) and *R*-(-)-mandelic acid (7.14 g, 0.047 mol) was added in one portion. The solution was slowly added into toluene (650 mL) whilst distilling the azeotrope under vacuum such that the volume was kept constant. When all of the ethanol had been added

This product (16.07 g, 87% ee) was added to a

methanobenzocyclooctene-11,3'-[1,2,5]thiadiazole] 1',1'-dioxide was synthesised from the triflate Intermediate D using the method described in Example 24, Step 1. Three portions of 100 mg of the aforementioned boronate were weighed into separate microwave reaction tubes. To each tube were added toluene (2 mL), ethanol (1 mL), water (1 mL), 2-bromothiazole (28 µL), potassium carbonate (142 mg) and [1,1'-bis(diphenylphosphino)ferrocene]dichloropalladium(II), complex with dichloromethane (17 mg). The reaction tubes were sealed and the mixtures heated in a microwave at 100°C for 5 min. Thin-layer chromatographic analysis indicated incomplete reaction, therefore a spatula tipful of the palladium catalyst was added to each reaction mixture before re-sealing and heating for a further 5 min at 100°C. The reaction mixtures were combined, poured into satd. NaHCO₃(aq) and extracted with ethyl acetate. The organic layer was washed with brine, dried over Na₂SO₄ and concentrated to give a brown gum. 5 Catalytic *N,N*-dimethylformamide (2 drops) was added to a stirred solution of the acid Intermediate A (0.75 g, 1.86 mmol) and oxalyl chloride (0.65 mL, 7.4 mmol) in dry dichloromethane (20 mL) at room temperature under nitrogen. The effervescent mixture was stirred at room temperature for 18 hours. Solvents and excess reagents were removed *in vacuo* to give
10 the acid chloride as an orange foam.

A solution of isopropylmagnesium chloride (2M in THF; 5.6 mL, 11.2 mmol) was added at -78°C to a stirred solution of ethyl hydrogen malonate (0.74 g, 5.6 mmol) in dry tetrahydrofuran (20 mL) under nitrogen. After 25 minutes stirring at -78°C, a solution of the acid chloride in tetrahydrofuran (10 mL) was added. The orange solution was warmed to room temperature. After stirring at room temperature for 1.5 hours, 1 M aqueous hydrochloric acid (45 mL) was added. When effervescence had subsided, the mixture was extracted with ethyl acetate (2 x 50 mL). A solution of 3,3-dibromoprop-2-enoyl chloride (1.60 g, 6.44 mmol) (prepared as described in *Synthesis*, 1984, 434) in dry dichloromethane (10 mL) was added dropwise by syringe to a stirred solution of ethyl 3-methylcarbazate (0.77 g, 6.50 mmol) (prepared as described in *Arch. Pharm.* 1971, **304**, 706) and triethylamine (0.90 mL, 6.50 mmol) in dry dichloromethane (10 mL) at 0°C under nitrogen. After 2 hours, the solution was washed with 0.2M hydrochloric acid (30 mL). The aqueous washings

were extracted with dichloromethane (20 mL). The combined organic layers were washed with brine (20 mL), dried (Na_2SO_4) and concentrated to give a pink oil (2.01 g). A solution of sodium hydroxide (2.10 g, 53 mmol) in water (42 mL) was warmed to 60°C and added to the oil. The mixture
5 was stirred at 60°C for 25 min, then cooled slowly to room temperature over 1 hour and allowed to stand at room temperature for 1 hour. The solution was acidified by dropwise addition of concentrated hydrochloric acid. After chilling for 30 min, the white precipitate was collected. The aqueous layer was extracted with 10% methanol – dichloromethane (60
10 mL). The collected solids were dissolved in the organic extract, and the solution was dried (Na_2SO_4) and concentrated to give a yellow solid. The solid was rinsed with diethyl ether and dried under vacuum to give 1-methyl-3-bromo-5-pyrazolone as a yellow powder (0.56 g, 49%).

Step 2: 1-methyl-3-bromo-5-(nonafluorobutanesulfonyloxy)pyrazole

A solution of sodium bis(trimethylsilyl)amide in tetrahydrofuran (1M, 0.70 mL, 0.70 mmol) was added at -78°C under nitrogen to a stirred solution of
20 1-methyl-3-bromo-5-pyrazolone from Step 1 (0.10 g, 0.565 mmol) in dry tetrahydrofuran (2 mL). After 10 min, nonafluorobutanesulfonyl fluoride (0.13 mL, 0.70 mmol) was added dropwise. The resulting gel was warmed to room temperature and stirred for 1 hour. The solution was diluted with water (10 mL) and extracted with ethyl acetate (2 x 10 mL). The extracts
25 were dried (Na_2SO_4) and concentrated. Flash column chromatography on silica, eluting with 10% ethyl acetate – isohexane, gave 1-methyl-3-bromo-5-(nonafluorobutanesulfonyloxy)pyrazole (0.204 g, 79%) as a colourless oil.

The solution was stirred at 60°C for 18 hours then cooled, diluted with water (30 mL), and extracted with ethyl acetate (2 x 20 mL). The extracts were dried (Na₂SO₄) and concentrated. Flash column chromatography on silica, eluting with 10% ethyl acetate – isohexane, gave 1-methyl-3-bromo-5-(5-methylpyridin-2-yl)pyrazole (0.081 g, 41%) as a yellow solid. MS (ES⁺) 252, 254 ([MH]⁺).

PCT/GB 03/01763

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 18
because they relate to subject matter not required to be searched by this Authority, namely:
Although claim 18 is directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 8.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
